Taupo zone volcanism, extension and large silicic eruptions (Magmatism-Volcanism-Tectonism)

Colin J.N. Wilson: Victoria University of Wellington
J.V. Rowland: University of Auckland

GNS image by Lloyd Homer
Taupo Volcanic Zone (TVZ): the plate boundary setting

- Slightly oblique convergence
- Oceanic plateau (Hikurangi Plateau), Cretaceous LIP being subducted
- Modest convergence rates (40-45 mm per year)
- No obvious plate-tectonic reason for unusual behaviour
TVZ: a geographical outline

Three segments to TVZ:

1. Northern – normal andesite-dacite arc, continuous with Kermadec arc
2. Southern – normal andesite-dacite arc
3. Central – unusual, dominated by silicic (rhyolitic) eruptions from caldera volcanoes (labelled coloured outlines) Magma volumes and rates are an order of magnitude higher than for cone centres
(Central) TVZ: a chronological outline

Three main time periods in (central) TVZ history:

1. Old TVZ: 2.0 Ma to ~350 ka. Many uncorrelated units

2. Young TVZ: 350 ka (Whakamaru Group eruptions) to present day. Most large eruptions documented

3. Modern TVZ: 61 ka to present, representative of the active state of the system. All eruptions known?
Modest eruption volumes and rates for non-rhyolite lithologies

Non-rhyolitic lithologies in the young TVZ

Key points:

- Total volumes an order of magnitude lower than that for rhyolite over the past 350 ka
- No systematic time-progression from andesite to rhyolite
- No arc/back-arc separation
Central TVZ: most productive rhyolitic volcanic zone on Earth (~13 km³ of rhyolite magma erupted per 1000 yr for the past ~61 kyr)

The volcanic flux only makes up ~25% of the natural heat output: Total of ~50 km³ magma equivalent intruded or extruded per 1000 yr under central TVZ

Close interplay with tectonic riftling processes

Vents active since 61 ka
- silicic (rhyolite >> dacite)
- andesitic
- basaltic

Central TVZ: what are the major inferences from volcanic and tectonic studies?

1. What are the major first-order observations from a regional picture? Variations in space and time.

Vents active since 61 ka
- silicic (rhyolite >> dacite)
- andesitic
- basaltic

Warm colours denote geothermal systems (total natural heat flux of ~4.2 GW)

Magnitude-frequency relationships for silicic eruptions?

Average of one eruption per 900 years: 5 OM variations in erupted volumes; 3 OM variations in repose periods

Forecasting, anyone?

Eruptions after the 25.4 ka Oruanui event ($n = 39$):

Relationships between volumes of magma erupted and repose periods before or after events are not systematic (chaotic?)

What if eruption volumes and repose intervals are driven by a non-linear interaction between two linear phenomena: rates of magma production and rates of tectonism?
Central TVZ: what are the major inferences from volcanic and tectonic studies?

2. What is the resulting crustal structure, and how does it influence inferences about the deep heat sources?

Vents active since 61 ka
- silicic (rhyolite >> dacite)
- andesitic
- basaltic

Warm colours denote geothermal systems (total natural heat flux of ~4.2 GW)

Central TVZ: rifting arc environment (as opposed to arc/back-arc pairing), with thinned, young (Permian or later) crust. Crustal lithologies with $V_p$ values appropriate to dominant quartz-feldspathic densities (and hence lithologies) only 15-16 km thick. Limits depths/pressures for silicic systems.

Details subject to variations...
Central TVZ: what are the major inferences from volcanic and tectonic studies?

3. Where are the deep magma sources that are driving the volcanism and deep geothermal fluid upflows?

Vents active since 61 ka
- silicic (rhyolite >> dacite)
- andesitic
- basaltic

Warm colours denote geothermal systems (total natural heat flux of ~4.2 GW)

Some paradoxes and contradictions inherent in our current data sets and knowledge. Zones of crustal melt implied to be present from MT studies do not relate to volcanism in some key cases, and the ‘rift axis’ defined from surface faulting studies is not where the greatest surface heat flows are occurring.

Central TVZ: what are the major inferences from volcanic and tectonic studies?

Not always where they might be expected to be.

From Heise et al., 2010, GRL 37, L10301
Central TVZ: what are the major inferences from volcanic and tectonic studies?

4. Volcano-tectonic interactions during eruptions: the chicken vs the egg.

Vents active since 61 ka
- silicic (rhyolite >> dacite)
- andesitic
- basaltic

Warm colours denote geothermal systems (total natural heat flux of ~4.2 GW)

Modern central TVZ: dependence versus independence of volcanic systems, and a volcano-tectonic connection?
Pairing of eruptions through tectonic linkages: example of the Mamaku – Ohakuri pair at ~240 ka

From: Gravley et al. 2007, GSAB 119, 18

Modern central TVZ: dependence versus independence of volcanic systems, and a volcano-tectonic connection?

No more than weeks to months between two large eruptions
Reconstructing magma bodies through crystal-specific investigations

Studies of individual mineral species yields valuable information about the sources of components that go to make up a large magma body (the ~530 km$^3$ Oruanui in this case). The key questions are, though, relate to the rates of the processes involved.

From: Wilson et al., 2006, J Petrol 46, 35
How rapidly was the Oruanui magma body assembled?

Textural relationships between orthopyroxene (Opx) and amphibole, suggest upward movement of crystals from the mush zone into the melt dominant body. These matched by compositional changes.

Diffusional boundary in Opx marks entry into the melt-dominant body. Fe-Mg diffusion rates then used to measure residence time in the magma body. Maximum 1600 years, peak 230 years (using final magmatic temperature on eruption). Tectonic control on magmatic processes?

From: Allan et al., 2013, Contrib Mineral Petrol, in press
What controlled the onset and modulation of the Oruanui eruption?

Two geochemically distinct but closely adjacent magma factories in action independently prior to the Oruanui event:

- Okaia (Oruanui-type magma), ~28.5 ka
- Poihipi (NE-dome type magma), ~27 ka

See Sutton et al., 1995, JVGR 68, 253; Wilson & Charlier, 2009, J Petrol 50, 875
Early phases of the Oruanui eruption

Two types of pumice present in the early Oruanui deposits

After Allan et al.: Geology 40, 563 (2012)
What controlled the onset and modulation of the Oruanui eruption?

Syn-eruptive rifting the key to (a) lateral transport of independent magmas to a common vent and (b) understanding how the Oruanui eruption started and stopped in its early phases, as well as explaining the escalation into later activity.
Longer-term interactions of magmatism and tectonics: fossil shorelines of Lake Taupo

From: Manville & Wilson, 2003: J Geol Soc Lond 160, 3; 2004, NZ J Geol Geophys 47, 525
Information from the post-Oruanui shorelines

Recorded values for the post-Oruanui highstand terrace (blue trend line)
Recorded values for the post-Oruanui highstand terrace (blue trend line) contrasted with predicted alignment from modern deformation rates
